

Quick steps to nqch (paul) server access

Step 1 — Find or create your SSH public key

Check what keys you already have:

```
ls ~/.ssh/*.pub
```

If you see a file listed (e.g. `id_ed25519.pub`, `id_rsa.pub`, or similar), display it:

```
cat ~/.ssh/id_ed25519.pub
```

(replace the filename with whatever showed up in the `ls` command above)

If `ls` says "No such file or directory", you don't have a key yet — create one:

```
ssh-keygen -t ed25519 -C "your_email@example.com"
```

Press Enter to accept all default prompts (including empty passphrase, unless you want one). Then run the `cat` command above to display your new key.

Step 2 — Send me that key

Copy the full output (starts with `ssh-ed25519` or `ssh-rsa`, ends with your email/comment) and send it to me. I'll add it to the server.

Step 3 — Wait for my confirmation, then test:

```
ssh mustafa@10.246.80.228
```

You should log in without being asked for a password. If it works, continue to Step 4.

Step 4 — (Optional but recommended) Add a shortcut to your SSH config

Open your SSH config file:

```
nano ~/.ssh/config
```

Add this block at the end (paste it exactly):

```
# Paul server for CQT Qibo user mustafa
Host cqt-paul-server-mustafa
  HostName 10.246.80.228
  User mustafa
```

Save and exit (in `nano`: Ctrl+O, Enter, Ctrl+X).

From now on, you can just type:

```
ssh cqt-paul-server-mustafa
```

instead of the longer `ssh mustafa@10.246.80.228` — both will work identically.
